TITLE: Logical ring in a virtual single machine

ABSTRACT:

A multi-processor, multi-tasking virtual machine comprises processes, messages, and contexts. Processes communicate only through messages. Processes may be grouped into contexts of related processes. Communication may be made between processes in different or related contexts or at the same context level. According to one message transmission mode, a message may be sent to each process with a given name within one context, thus ensuring that all processes with the same name at the same context level can be communicated with individually without knowing how many there are or where they are located.

US PAT NO: 5,014,192 [IMAGE AVAILABLE] L6: 2 of 2  
TITLE: System for locating a file in a logical ring by  
sequentially forwarding access request with file system  
name and file name

# ABSTRACT:

A data management system used by a digital computer system comprises a plurality of individual file systems which are connected together in a logical ring configuration around which file requests travel. File requests may be transmitted by the user to the "next" file system in the ring relative to the user.

File requests optionally may or may not specify a file system name. If a file system name is specified, then the request is forwarded unidirectionally around the logical ring until either that file system name is found or the request returns to its starting point. If no file system name is specified, then an attempt is made to satisfy the request on each file system in turn until either the request is satisfied or the request returns to its starting point.

RESOURCE to ii) limit access to

each stored RESOURCE" is taught by East, et al. in the form of "access control list"s which tell which users may access an object (East, et al., col. 2, lines 27-35).

Claim 6, independent: The "multiple SERVERs" is not explicitly taught by Khoyi, et al. or East, et al. but is rejected as obvious and common at the time of the invention as distributed systems with multiple servers were well-known. One of ordinary skill in the art at the time of the invention would have been motivated to apply the system of Khoyi, et al. as modified by East, et al. to a distributed multiserver system as East, et al. states that the system is designed for multiuser systems (East, et al., abstract), which, at the time of the invention, would be most economical as a LAN. The "means for
